(54) Title: METHOD AND APPARATUS FOR SUPPORTING ADAPTIVE MULTI-RATE (AMR) DATA IN A CDMA COMMUNICATION SYSTEM

(57) Abstract: Techniques to support adaptive multi-rate (AMR) coded data in a cdma2000 communication system. A number of AMR modes are defined for speech information (of various rates), silence descriptor (SID) (of various types), and blank frame. The speech and SID data are provided in frames conforming to frame formats defined by the cdma2000 system. A CRC is used for each AMR frame (e.g., 12-bit CRC for speech and 8-bit CRC for SID). The AMR data and CRC bits are further coded with a conventional encoder. Blind rate detection is used to detect the frame rate of the transmitted AMR frames. To support blind rate detection, the number of bits provided to the CRC generator is different for each blind rate to be detected. If two or more blind rates have the same number of bits (such as for SID), then format bits are provided to distinguish between these rates.

WO 01/52467 A1

METHOD AND APPARATUS FOR SUPPORTING ADAPTIVE MULTI-RATE (AMR) DATA IN A CDMA COMMUNICATION SYSTEM

5 BACKGROUND OF THE INVENTION

I. Field of the Invention

10 The present invention relates to data communication. More particularly,
the present invention relates to novel and improved method and apparatus for
supporting the adaptive multi-rate (AMR) speech codec data in a cdma2000
communication system.

15 II. Description of the Related Art

Wireless communication systems are widely deployed to provide
various types of communication such as voice, data, and so on. These systems
may be based on code division multiple access (CDMA), time division multiple
access (TDMA), or some other modulation techniques. A CDMA system
20 provides certain advantages over other types of system, including increased
system capacity.

A system may be designed to support one or more standards such as (1)
the "TIA/EIA/IS-95-B Mobile Station-Base Station Compatibility Standard for
Dual-Mode Wideband Spread Spectrum Cellular System" (the IS-95 standard),
25 (2) the standard offered by a consortium named "3rd Generation Partnership
Project" (3GPP) and embodied in a set of documents including Document Nos.
3G TS 25.211, 3G TS 25.212, 3G TS 25.213, and 3G TS 25.214 (the W-CDMA
standard), (3) the standard offered by a consortium named "3rd Generation
Partnership Project 2" (3GPP2) and TR-45.5 (the cdma2000 standard, formerly
30 called IS-2000 MC), or (4) some other standard. These standards are
incorporated herein by reference.

Each standard specifically defines the processing of data for
transmission on the forward and reverse links. For example, speech
information may be coded at a particular data rate, formatted into a defined
35 frame format, and processed (e.g., error correction and/or detection encoded,
interleaved, and so on) in accordance with a particular processing scheme. The
frame formats and processing defined by a particular standard (e.g., cdma2000
standard) is likely to be different from those of other standards (e.g., W-CDMA
standard).

The W-CDMA standard defines an Adaptive Multi-Rate (AMR) speech coding scheme whereby speech information may be encoded based on one of a number of possible data rates and the coded speech data is provided in a particular format that depends on the selected data rate.

- 5 For compatibility and interoperability between various types of communication system, it is highly desirable to provide a cdma2000 system capable of supporting AMR coded speech data.

SUMMARY OF THE INVENTION

10

- The present invention provides techniques to support adaptive multi-rate (AMR) coded data in a cdma2000 communication system. A number of AMR modes are defined for speech information, silence descriptor (SID), and blank frame, as described in further detail below. The AMR modes for speech
15 information support a number of AMR speech data rates (e.g., as defined by the AMR standard identified below). The AMR modes for SID data support a number of types of SID. The speech and SID data are provided in 20 msec frames.

- For an implementation in a cdma2000 system, the AMR modes are
20 supported by a number of radio configurations on the forward and reverse links using the flexible rate feature supported by the cdma2000 standard. In an embodiment, a 12-bit CRC is selected for AMR speech frames and an 8-bit CRC is selected for SID frames. These CRC selections provide good performance while minimizing the number of overhead bits used for each frame. The AMR
25 data and CRC bits are further coded with a convolutional encoder having a particular code rate, as defined for the radio configurations by the cdma2000 standard.

- In another aspect, blind rate detection is used to detect the frame rate of received AMR frames. With blind rate detection, each received frame is
30 decoded based on a number of hypotheses, with each hypothesis associated with a particular set of decoding parameter values used to decode the received frame. To support blind rate detection, the number of bits provided to the CRC generator is different for each of the possible blind rates to be detected (i.e., each of the AMR modes desired to be detected separately). If two or more
35 blind rates have the same number of bits, then additional overhead (format) bits are provided to distinguish between these rates.

The invention further provides methods and system elements that implement various aspects, embodiments, and features of the invention, as described in further detail below.

5 **BRIEF DESCRIPTION OF THE DRAWINGS**

The features, nature, and advantages of the present invention will become more apparent from the detailed description set forth below when taken in conjunction with the drawings in which like reference characters
10 identify correspondingly throughout and wherein:

FIG. 1 is a diagram of a spread spectrum communication system that supports a number of users;

FIG. 2 is a block diagram of the processing for an AMR data transmission in accordance with the W-CDMA standard;

15 FIG. 3 is a block diagram of the processing for an AMR data transmission in accordance with the cdma2000 standard;

FIGS. 4 and 5 are diagrams showing the frame formats for the supported AMR modes for the forward and reverse links, respectively; and

FIG. 6 is a block diagram of an embodiment of a receiving unit capable
20 of processing an AMR frame.

DETAILED DESCRIPTION OF THE SPECIFIC EMBODIMENTS

FIG. 1 is a diagram of a spread spectrum communication system 100 that
25 supports a number of users. System 100 provides communication for a number of cells, with each cell being serviced by a corresponding base station 104. Various remote terminals 106 are dispersed throughout the system. Each remote terminal 106 may communicate with one or more base stations 104 on the forward and reverse links at any particular moment, depending on whether
30 or not the remote terminal is active and whether or not it is in soft handoff. As shown in FIG. 1, base station 104a communicates with remote terminals 106a, 106b, 106c, and 106d, and base station 104b communicates with remote terminals 106d, 106e, and 106f.

A system controller 102 couples to base stations 104 and may further
35 couple to a public switched telephone network (PSTN). System controller 102 provides coordination and control for the base stations coupled to it. System controller 102 further controls, via base stations 104, the routing of telephone calls among remote terminals 106, and between remote terminals 106 and the

users coupled to PSTN (e.g., conventional telephones). System controller 102 is also referred to as a base station controller (BSC).

System 100 may be designed to conform to the cdma2000 standard, the W-CDMA standard, some other standard, or a combination thereof.

5 FIG. 2 is a block diagram of the processing for an AMR data transmission in accordance with the W-CDMA standard. An adaptive multi-rate (AMR) speech coder 212 receives and codes a speech signal and provides coded speech data that is grouped into three classes labeled as Class A, Class B, and Class C. Class A are the most important bits, Class B bits are the next most
10 important, and Class C bits are the least important. Because of the designated difference in importance, the bits for each class are transmitted via a different "transport" channel capable of providing different processing (e.g., error correction and detection coding, rate matching, and so on), which may be selected to be commensurate with the level of importance of the class. For
15 example, convolutional encoding and cyclic redundancy check (CRC) may be employed for Class A bits, convolutional encoding but no CRC may be employed for Class B bits, and no convolutional encoding or CRC may be employed for Class C bits.

 In the specific implementation shown in FIG. 2, Class A bits are CRC
20 coded (block 222a), convolutionally encoded (block 224a), rate matched (block 226a), and interleaved (block 228a) within a transport channel processor 220a. Class B bits are convolutionally encoded (block 224b), rate matched (block 226b), and interleaved (block 228b) within a transport channel processor 220b. And Class C bits are rate matched (block 226c) and interleaved (block 228c)
25 within a transport channel processor 220c. The processed bits from transport channel processors 220a through 220c are then multiplexed into a coded composite transport channel (CCTrCH) by a transport channel multiplexer 230, and the CCTrCH is further demultiplexed into one or more physical channel streams by a physical channel demultiplexer 232. Each (20 msec) frame on each
30 physical channel stream is further interleaved (block 234), and the resultant data stream comprises the data for the physical channel.

 The data processing for the W-CDMA standard is described in further detail in the W-CDMA standard documents and in U.S Patent Application Serial No. 09/678,645, entitled "DATA BUFFER STRUCTURE FOR PHYSICAL
35 AND TRANSPORT CHANNELS IN A CDMA SYSTEM," filed October 3, 2000, assigned to the assignee of the present application and incorporated herein by reference. AMR coder 212 may be designed to conform to the "ETSI EN 301 704

Digital Cellular Telecommunications System; Adaptive Multi-Rate (AMR) Speech Transcoding" (the AMR standard).

FIG. 3 is a block diagram of the processing for an AMR data transmission in accordance with the cdma2000 standard. An adaptive multi-rate (AMR) speech coder 312 receives and codes a speech signal and provides coded speech data that is grouped into three classes labeled as Class A, Class B, and Class C. AMR coder 312 may also be designed to conform to the aforementioned AMR standard. The three classes of bits are provided to a concatenation unit 321 that forms data blocks, with each data block being transmitted in a frame and having a combination of bits from Class A, Class B, and possibly Class C. Each data block is then CRC coded (block 322), formatted (block 323), convolutionally encoded (block 324), rate matched (block 326), and interleaved (block 328). The resultant data stream comprises the data for a traffic channel (e.g., a fundamental or supplemental channel in the cdma2000 system).

FIG. 3 shows an implementation for supporting AMR speech data in the cdma2000 system. In an embodiment, the Class A, B, and C bits are treated as Class A bits (the most reliable bits), and error-correcting coding and CRC are provided for all three classes of bits. For an AMR speech frame, one CRC is generated for all data bits (i.e., all three classes of bits). A single tailed-off convolutional encoder is also used for all bits in the frame.

The CRC coding in block 322 generates a number of CRC bits (e.g., an 8-bit or 12-bit CRC value) for each received data block based on a particular generator polynomial. The number of CRC bits to be included with each data block is selected to provide a high likelihood of correctly detecting a whether or not a frame has been received in error, while minimizing the number of overhead bits. In an embodiment, an 8-bit CRC value is employed for lower rate frames (e.g., having 80 data bits or less), and a 12-bit CRC value is employed for higher rate frames (e.g., having up to 267 data bits). The polynomial generators used to generate the 8-bit and 12-bit CRC values may be as follows:

$$g(x) = x^{12} + x^{11} + x^{10} + x^9 + x^8 + x^4 + x + 1, \quad \text{for 12-bit CRC}$$

$$g(x) = x^8 + x^7 + x^4 + x^3 + x + 1 \quad \text{for 8-bit CRC}$$

CRC values of other lengths (e.g., 6-bit, 10-bit, 16-bit, and so on) may also be used and are within the scope of the invention. Also, other types of frame quality indicator may also be used instead of CRC, and this is also within

the scope of the invention. Other types of frame quality indicator that may be used include decoder metrics, re-encoded symbol error rate, and others.

The frame formatting in block 323 generates a data frame of a defined format. For some AMR modes, additional overhead bits may be added with
5 the data bits such that the frames for these modes have a particular fixed length (e.g., 43 bits), as described in further detail below. Also, a number of encoder tail bits (e.g., 8 bits of zeros) are appended to the end of each data block. These tail bits are used to flush the convolutional encoder to a known state (all zeros) at end of each data block, so that the encoding of the next data block starts from
10 the known state.

The rate matching in block 326 may be achieved by repeating each bit in a frame N times (wherein N may be 1, 2, 4, 8, or some other value) and puncturing (i.e., deleting) zero or some of the bits in accordance with a particular puncturing pattern. The puncturing pattern may be generated based
15 on a particular algorithm. For AMR data, the puncturing may be achieved as described in U.S Patent Application Serial No. 09/587,168, entitled "METHOD AND APPARATUS FOR PUNCTURING CODE SYMBOLS IN A COMMUNICATIONS SYSTEM," filed October 6, 2000, assigned to the assignee of the present application and incorporated herein by reference.

20 The data format and processing for the cdma2000 standard is described in further detail in the cdma2000 standard documents.

Table 1 lists the AMR modes specified by the W-CDMA standard, and the number of bits for Classes A, B, and C for each AMR mode. The classification of the bits into three classes, the number of bits for each class,
25 and/or the total number of bits for each data block may be different from those listed in Table 1.

As shown in Table 1, AMR modes 0 through 7 are assigned to eight different AMR speech data rates ranging from 4.75 kbps to 12.2 kbps. AMR modes 8 through 11 are used for sending different types of silence descriptor
30 (SID) information. AMR modes 12-14 are reserved for future use, and AMR mode 15 represents no data transmission. As shown in Table 1, the total number of bits in a frame ranges from 1 to 244. The reverse link (RL) speech rate bits in the last column of Table 1 are used to specify the reverse link rate, and are only needed for a forward link frame.

Table 1 - AMR Modes

AMR Mode Index	Mode Description	Number of Bits/20-msec Block				
		Total Class A, B, & C	Class A	Class B	Class C	RL Speech Rate
0 (AMR4.75)	4.75 kbps Speech	95	39	56	0	3
1 (AMR5.15)	5.15 kbps Speech	103	49	54	0	3
2 (AMR5.90)	5.90 kbps Speech	118	55	63	0	3
3 (AMR6.70)	6.70 kbps Speech	134	58	76	0	3
4 (AMR7.40)	7.40 kbps Speech	148	61	87	0	3
5 (AMR7.95)	7.95 kbps Speech	159	75	84	0	3
6 (AMR10.2)	10.2 kbps Speech	204	65	99	40	3
7 (AMR12.2)	12.2 kbps Speech	244	81	103	60	3
8	GSM-AMR SID	39	39	0	0	3
9	GSM-EFR SID	42	42	0	0	3
10	IS-641 SID	38	38	0	0	3
11	PDC-EFR SID	37	37	0	0	3
12-14	For Future Use	TBD	TBD	TBD	TBD	3
15	No Transmission	0	0	0	0	3

In an embodiment, the frames for the four types of SID (i.e., for AMR modes 8 through 11) are designed to have the same length (e.g., 46 bits for the forward link and 43 bits for the reverse link). The same frame length allows for easy detection of SID frames from other frame types. The length of the SID frames is determined based on the most number of data bits to be transmitted for a SID (i.e., 42 bits, for AMR mode 9) and a sufficient number of additional format bits (e.g., one bit) to identify and distinguish the four SID types.

Table 2 lists a specific definition of the format bits for the four SID types for the forward link. A maximum rate indicator (MR) bit denotes whether or not the SID frame is for AMR mode 9. If the SID frame is not for AMR mode 9, then two additional format bits are used for the mode indicator (MI), which identify the SID frame as either AMR mode 8, 10, or 11. The remaining bits not used for SID data or as format bits are reserved, as shown in Table 2.

Table 2 - Forward Link Information Bits for the SID Modes

AMR Mode Index	Format Bits		Bits/Frame			
	Max Rate Indicator (MR)	Mode Indicator (MI)	Reserved	SID Data	RL Rate Bits	Total Infor- mation Bits
8	'0'	'00'	1	39	3	46
9	'1'	—	0	42	3	46
10	'0'	'10'	2	38	3	46
11	'0'	'11'	3	37	3	46

Table 3 lists a specific definition of the format bits for the four SID types for the reverse link. The max rate indicator (MR) bit and mode indicator (MI) bits are defined the same as for the forward link. However, 43 bits are included in each SID frame since the three reverse link rate bits are not required for the reverse link SID frame.

Table 3 – Reverse Link Information Bits for the SID Modes

AMR Mode Index	Format Bits		Bits/Frame		
	Max Rate Indicator (MR)	Mode Indicator (MI)	Reserved	SID Data	Total Infor- mation Bits
8	'0'	'00'	1	39	43
9	'1'	—	0	42	43
10	'0'	'10'	2	38	43
11	'0'	'11'	3	37	43

FIG. 4 is a diagram showing the frame formats for the supported AMR modes on the forward link. As shown in FIG. 4 and Table 1, the frames for AMR modes 0 through 5 include a number of Class A bits and a number of Class B bits, with the specific number of bits in each class being dependent on the particular AMR mode. The frames for AMR modes 6 and 7 include a number of bits for Class A, B, and C, again with the specific number of bits in each class being dependent on the particular AMR mode. For each frame, the left-most bits are sent first.

The frames for AMR modes 8 through 11 (i.e., the SID frames) include the SID data and the maximum rate indicator (MR) bit, and may further include

the mode indicator (MI) bits and reserve bits, as shown in FIG. 4 and Table 2. The frame for AMR mode 15 includes one reserved bit. The forward link frame for each AMR mode further includes three reverse link speech rate bits.

FIG. 5 is a diagram showing the frame formats for the supported AMR modes on the reverse link. The frames for AMR modes 0 through 11 on the reverse link have the same format as the corresponding frames on the forward link, minus the three reverse link speed rate bits. The frame for AMR mode 15 includes four reserve bits.

In accordance with an aspect of the invention, blind rate detection is used to detect the transmitted frames for the supported AMR modes. With blind rate detection, each received frame is decoded based on a number of hypotheses, with each hypothesis associated with a particular set of decoding parameter values used to decode the received frame. For example, a hypothesis may hypothesize a particular data rate, code rate, and so on, used at the transmitting source for the received frame. The hypothesis that yields the best quality metric (e.g., a CRC checked frame) is deemed as the correct one, and the frame decoded based on this hypothesis is selected as the transmitted frame.

To support blind rate detection, the number of bits provided to the CRC generator should be different for each of the possible blind rates to be detected (i.e., each of the AMR modes desired to be detected separately). If two or more blind rates have the same number of bits, then additional overhead bits are needed to distinguish between these rates.

For any particular negotiated AMR service, at most four speech rates are possible. In this case, the AMR modes listed in Table 1 may be supported, for example, by six different frame rates. These six frame rates may include four frame rates used for speech data (AMR mode 0 through 7), one frame rate used for silence descriptor (SID) (AMR modes 8 through 11), and one frame rate used for no transmission (AMR mode 15). The frames for the four types of SID (for AMR modes 8 through 11) may be defined to have the same length (e.g., 43 bits) and thus share the same frame rate.

At the receiving unit, there are six possible blind rates to detect. Since the SID frames for the four SID types share the same frame rate, the blind rate detection is only able to determine whether or not a received frame is a SID frame. One or more additional format bits are included in each SID frame to allow for identification of the particular SID type, as described above in Tables 2 and 3. The use of blind rate detection obviates the need to send overhead bits in each frame to identify the particular AMR mode being used.

In a cdma2000 system, voice and packet data may be transmitted on one or more traffic channels over the forward and reverse links. (A traffic channel is akin to a physical channel in the W-CDMA system.) In the cdma2000 system, voice data is typically transmitted over a fundamental channel (FCH), traffic data is typically transmitted over a supplemental channel (SCH), and signaling may be transmitted over a dedicated control channel (DCCH). The FCH, DCCH, and SCH are different types of traffic channel. To receive a high-speed data transmission on the SCH, a remote terminal is also typically assigned a FCH or DCCH.

In the cdma2000 system, each assigned traffic channel is associated with a particular radio configuration (RC) that defines the traffic channel's characteristics. These characteristics may be defined by various physical layer parameters such as the (convolutional or Turbo) code rate (R), the modulation characteristics, the spreading rate (SR), and so on. Each radio configuration further supports up to ten different data rates ranging from 1.5 Kbps to 1.0368 Mbps, which correspond to 30 to 20,736 bits per 20 msec frame. The radio configurations also support flexible rates whereby data may be transmitted at data rates ranging from 750 bps to 1.0368 Mbps.

Table 4 lists the radio configurations and the associated parameter values for some of the flexible data rates for the forward fundamental channel, as defined by the cdma2000 standard. The data rates listed in Table 4 may be used to support the AMR modes listed in Table 1.

Table 4 – Forward Traffic Channel Frame Structure for the Fundamental Channel and Some Supported Flexible Data Rates

Radio Config.	Number of Bits/Frame			
	Total	Information	CRC	Tail
3, 4, 6, and 7	17 to 96	1 to 80	8	8
	21 to 192	1 to 172	12	8
5, 8, and 9	17 to 72	1 to 56	8	8
	21 to 288	1 to 268	12	8

Table 5 lists the code rate and interleaver size for radio configurations 3 through 9 for the forward link, as defined by the cdma2000 standard.

Table 5 – Radio Configuration Characteristics for the Forward Fundamental Channel

Radio Config.	Code Rate	Interleaver Size
3	1/4	768
4	1/2	384
5	1/4	768
6	1/6	1152
7	1/3	576
8	1/4	1152
9	1/2	576

5

In accordance with an aspect of the invention, the AMR modes listed in Table 1 are supported by a number of radio configurations on the forward and reverse links using the flexible rate feature supported by the cdma2000 standard. In an embodiment, a 12-bit CRC is selected for AMR speech frames (AMR modes 0 through 7) and an 8-bit CRC is selected for SID frames (AMR modes 8 through 11). These CRC selections provide good performance while minimizing the number of overhead bits used for each frame.

Tables 6 through 12 show an embodiment for supporting the AMR modes listed in Table 1 using radio configurations 3 through 9, respectively, for the forward link. In each of these tables, the number of information bits (column 2) for the AMR speech frames (AMR modes 0 through 7) is the sum of the Class A, B, and C bits and the three RL speech rate bits. The number of information bits for each SID frame is the sum of the SID bits, the format bits, and the three RL speech rate bits. The encoder input (column 5) includes the total information bits from column 2 plus the 8 or 12 CRC bits (column 3) and the 8 tail bits (column 4). For each radio configuration, the code rate is defined by the cdma2000 standard. For a code rate of 1/4, four code bits are generated for each information bit, and the number of bits at the encoder output (column 6) is four times the number of bits provided to the encoder input. The interleaver size (column 7) is fixed for a particular radio configuration.

For radio configurations 3, 4, 6, and 7, the two highest AMR rates in modes 6 and 7 are not supported. These radio configurations are based on Rate Set 1 (9.6 kbps) where the maximum number of information bits per frame is

172 for the fundamental channel. To accommodate the higher AMR rates, a radio configuration based on Rate Set 2 (14.4 kbps), which provides up to 268 information bits per frame, can be used. For example, radio configurations 3 and 5 use a rate 1/4 encoder with a 768-symbol interleaver. However, radio configuration 5 supports up to 268 information bits per fundamental channel frame while radio configuration 3 only supports up to 172 information bits. The flexible rate parameters are the same for radio configurations 3 and 5 for the lower rate AMR modes, but radio configuration 5 is able to support all AMR modes listed in Table 1. Thus, for most AMR applications, radio configuration 5 may be used instead of radio configuration 3.

Table 6 - Forward Link Coding with Radio Configuration 3 (SR1, R = 1/4)

AMR Mode Index	Number of Bits/Frame					Inter-leaver Size
	Information	CRC	Tail	Encoder Input	Encoder Output	
0	98	12	8	118	472	768
1	106	12	8	126	504	768
2	121	12	8	141	564	768

Table 13 lists the radio configurations and the associate parameter values for some of the flexible data rates for the reverse fundamental channel, as defined by the cdma2000 standard. The flexible data rates listed in Table 13 may be used to support the AMR modes listed in Table 1. Radio configurations 3 through 6 on the reverse link utilize a rate 1/4 encoder and a 1536-symbol interleaver.

Table 13 – Reverse Traffic Channel Frame Structure for the Fundamental Channel and Some Supported Flexible Data Rates

Radio Config.	Number of Bits/Frame			
	Total	Information	CRC	Tail
3 and 5	17 to 96	1 to 80	8	8
	21 to 192	1 to 172	12	8
4 and 6	17 to 72	1 to 56	8	8
	21 to 288	1 to 268	12	8

10

Table 14 shows an embodiment for supporting the AMR modes using radio configuration 4 or 6 for the reverse link. In Table 14, the number of information bits (column 2) for the AMR speech frames (AMR modes 0 through 7) is the sum of the Class A, B, and C bits. The number of information bits for each SID frame is the sum of the SID bits and the format bits. The encoder input (column 5) includes the total information bits from column 2, the 8 or 12 CRC bits (column 3), and the 8 tail bits (column 4). For code rate 1/4, four code bits are generated for each information bit, and the number of bits at the encoder output (column 6) is four times the number of bits provided to the encoder input. The interleaver size (column 7) is defined by the cdma2000 standard.

Table 14 provides an implementation to support AMR data using radio configurations 4 and 6, which are based on Rate Set 2 (14.4 kbps). If radio configurations 3 and 5, which are based on Rate Set 1 (9.6 kbps), are used, the parameters would be the same as shown in Table 14 for radio configurations 4 and 6, with the exception that the two highest AMR rates for AMR modes 6 and 7 would not be supported. Thus, radio configuration 4 or 6 should be used instead of radio configurations 3 and 5.

25

12-14	TBD	TBD	8	TBD	TBD	1,536
15	0 + 4	12	8	24	96	1,536

To support the AMR modes listed in Table 1, signaling information associated with the AMR data may be sent (1) on a dedicated control channel (DCCH), (2) as a blank-and-burst frame on the traffic channel used to send the AMR data, or (3) via some other signaling mechanism. In an embodiment, signaling information for the AMR data is not sent as a "dim-and-burst" frame on the traffic channel.

FIG. 6 is a block diagram of an embodiment of a receiving unit 600 capable of processing an AMR frame. A demodulator (DEMOD) 612 receives and demodulates (e.g., despreads, decovers, and pilot demodulates) the samples from a preceding unit and provides demodulated frames. A multi-rate decoder 614 receives and decodes each demodulated frame in accordance with a set of rate hypotheses. Each rate hypothesis corresponds to a particular hypothesized rate for the received frame, and is associated with a particular set of processing (e.g., CRC, encoding, and interleaving) parameter values used for that rate. For each rate hypothesis, decoder 614 performs error-correction decoding and provides a decoded frame to a respective buffer 616. As shown in FIG. 6, a number of buffers 616a through 616f are provided for a number of

blind rates. For example, six buffers are used for the six blind rates to be detected for the AMR modes listed in Table 1, as noted above. Fewer or additional hypotheses for other blind rates may also be supported and are within the scope of the invention.

5 A rate detector 620 receives the decoded frames from buffers 616 and selects one of the decoded frames as the transmitted frame. In the embodiment shown in FIG. 6, rate detector 620 includes a CRC checker 622, a symbol error rate (SER) detector 624, a Yamamoto metric detector 626, a decoder metric detector 628, and a header checker 630. Rate detector 620 may be implemented
10 with only a subset of these checkers and detectors, or may employ different or additional checkers and detectors.

CRC checker 622 locally generates a CRC value for the data block in each decoded frame, and determines whether or not the locally generated CRC value matches the CRC value in the decoded frame. This CRC check is
15 performed for the decoded frames for all rate hypotheses. CRC checker 622 provides a number of check bits (e.g., C1, C2, and so on), one check bit for each of the possible blind rates being detected.

SER detector 624 receives the decoded bits from buffers 616 and an estimate of the received symbols via a line 618. SER detector 624 then re-
20 encodes the decoded bits, compares the re-encoded symbols to the received symbols, counts the number of discrepancies between the re-encoded symbols and the received symbols, and provides a symbol error rate (SER) indicative of the number of discrepancies. SER detector 624 provides a number of SER values (e.g., SER1, SER2, and so on), one SER value for each of the possible
25 blind rates being detected. The SER values for different frame rates are typically normalized to account for the difference in the number of symbols per frame. The SER values may be used, in addition to the CRC bits, to determine the rate and integrity of the current frame.

Yamamoto metric detector 624 provides a confidence metric based on a
30 difference between the selected path through a trellis and the next closest path through the trellis. While the CRC check is dependent on the bits in each of the decoded frames, the Yamamoto check is dependent on the frame processing prior to the decoding. Yamamoto detector 624 provides a number of Yamamoto values (e.g., Y1, Y2, and so on), one Yamamoto value for each of the
35 possible blind rates being detected.

Decoder metric detector 628 provides a metric indicative of the confidence of the decoded frames, such as the Viterbi decoder metric for the selected decoder trellis output path.

Rate detector 620 receives the CRC check bits from CRC checker 622, the SER values from SER detector 624, and the Yamamoto values from the Yamamoto detector 626. Rate detector 620 then determines which one of the possible rates is the actual rate of the received frame. Rate detector 620
5 employs a particular rate determination algorithm that weighs the results from the CRC check, SER detection, Yamamoto detection, or a combination thereof, and provides an estimate of the received frame rate based on these results. Once the rate of the received frame is determined, rate detector 620 provides a signal to the proper buffer 616 to provide the decoded frame, which may be
10 further processed. No frame may be provided if an erasure is declared (e.g., all CRC checks failed for the received frame), and the frame is deemed as being received in error. Alternatively or additionally, rate detector 620 may provide a signal indicative of a frame erasure if an erasure is declared.

For a received frame declared as being a SID frame, header checker 630
15 checks the format bits to determine which type of SID has been received. Header checker 630 may also provide a signal indicative of the particular SID type detected.

Decoder 614 may be implemented as a multi-rate Viterbi decoder described in U.S. Patent No. 5,710,784, entitled "MULTIRATE SERIAL VITERBI
20 DECODER FOR CDMA SYSTEM APPLICATIONS." Techniques for performing blind rate detection are described in U.S. Patent No. 5,751,725, entitled "METHOD AND APPARATUS FOR DETERMINING THE RATE OF RECEIVED DATA IN A VARIABLE RATE COMMUNICATION SYSTEM," U.S. Patent No. 5,774,496, entitled "METHOD AND APPARATUS FOR
25 DETERMINING DATA RATE OF TRANSMITTED VARIABLE RATE DATA IN A COMMUNICATIONS RECEIVER," and U.S. Patent No. 6,108,372, entitled "METHOD AND APPARATUS FOR DECODING VARIABLE RATE DATA USING HYPOTHESIS TESTING TO DETERMINE DATA RATE." These patents are assigned to the assignee of the present invention and incorporated
30 herein by reference.

In FIGS. 3 and 6, the processing units in the transmitting source (e.g., the base station) and the receiving device (e.g., the remote terminal) may be implemented by various means. For example, demodulator 612, decoder 614, and rate detector 620 in FIG. 6 may be implemented with hardware, software,
35 or a combination thereof. For a hardware implementation, the processing units may be implemented within one or more application specific integrated circuits (ASICs), digital signal processors (DSPs), programmable logic devices (PLDs),

controllers, micro-controllers, microprocessors, other electronic units designed to perform the functions described herein, or a combination thereof.

For a software implementation, these processing units may be implemented with modules (e.g., procedures, functions, and so on) that
5 perform the functions described herein. For example, the decoding, CRC check, SER detection, Yamamoto detection, blind rate determination, and/or other functions may be implemented with software code stored in a memory unit and executed by a processor.

For clarity, various aspects, embodiments, and features of the invention
10 have been described for a specific implementation for a cdma2000 system. However, other CDMA systems and standards may advantageously be implemented or adopted to support the AMR modes described herein and other modes.

The foregoing description of the preferred embodiments is provided to
15 enable any person skilled in the art to make or use the present invention. Various modifications to these embodiments will be readily apparent to those skilled in the art, and the generic principles defined herein may be applied to other embodiments without the use of the inventive faculty. Thus, the present invention is not intended to be limited to the embodiments shown herein but is
20 to be accorded the widest scope consistent with the principles and novel features disclosed herein.

WHAT IS CLAIMED IS:

CLAIMS

1. In a wireless communication system, a method for transmitting data
2 bits associated with an adaptive multi-rate (AMR) speech coder, comprising:
receiving a plurality of data bits associated with the AMR speech coder;
4 generating a plurality of frame quality indicator bits for the plurality of
data bits;
6 forming a formatted frame having included therein the plurality of data
bits and the plurality of frame quality indicator bits and conforming to a
8 particular frame format defined by the communication system; and
transmitting a representation of the formatted frame.
2. The method of claim 1, further comprising:
2 encoding the formatted frame with a particular encoder to generate an
encoded frame.
3. The method of claim 2, further comprising:
2 rate matching the encoded frame in accordance with a particular rate
matching algorithm.
4. The method of claim 1, wherein the plurality of frame quality
2 indicator bits comprise a plurality of cyclic redundancy check (CRC) bits.
5. The method of claim 4, wherein the plurality of frame quality
2 indicator bits comprise an 8-bit CRC value or a 12-bit CRC value.
6. The method of claim 1, wherein the formatted frame is associated
2 with one of a plurality of possible frame rates.
7. The method of claim 6, wherein the plurality of possible frame rates
2 includes four frame rates used for speech information, one frame rate used for a
silence descriptor (SID), and one frame rate used for a blank frame.
8. The method of claim 2, wherein the plurality of data bits are
2 representative of speech information.
9. The method of claim 8, wherein the plurality of data bits are
2 associated with one of a plurality of possible data rates.

10. The method of claim 9, wherein the formatted frame for each
2 possible data rate include a particular number of data bits, which is different
from the number of data bits in formatted frames for other possible data rates.

11. The method of claim 8, wherein the plurality of data bits includes
2 bits from a plurality of classes, and wherein each class is associated with a
respective level of importance.

12. The method of claim 11, wherein the generating and encoding are
2 performed on the plurality of classes of bits in the formatted frame.

13. The method of claim 11, wherein the plurality of classes of bits are
2 allocated respective sections of the formatted frame.

14. The method of claim 8, wherein the formatted frame with speech
2 information includes at least 12 frame quality indicator bits.

15. The method of claim 2, wherein the plurality of data bits are
2 representative of a silence descriptor (SID).

16. The method of claim 15, wherein the SID is one of a plurality of SID
2 types.

17. The method of claim 16, wherein the SID for each SID type includes
2 a particular number of bits that is different from the SIDs for other SID types.

18. The method of claim 16, further comprising:
2 appending, in the formatted frame, one or more format bits indicative of
a particular SID type of the SID included in the formatted frame.

19. The method of claim 18, wherein formatted frames for the plurality
2 of SID types have same frame length.

20. The method of claim 19, wherein the frame length for the plurality of
2 SID types is 43 bits or 46 bits.

21. The method of claim 15, wherein the formatted frame for the SID
2 includes at least 8 frame quality indicator bits.

22. The method of claim 1, further comprising:
2 transmitting signaling information associated with AMR data via a
signaling channel.

23. The method of claim 1, further comprising:
2 transmitting signaling information associated with AMR data in a
signaling frame on a traffic channel used to transmit the formatted frame.

24. The method of claim 1, wherein the wireless communication system
2 conforms to the cdma2000 standard.

25. A method for receiving data bits associated with an adaptive multi-
2 rate (AMR) speech coder, comprising:
receiving a frame having included therein a plurality of data bits
4 associated with the AMR speech coder;
detecting a frame rate of the received frame; and
6 extracting the plurality of data bits from the received frame based at
least in part on the detected frame rate.

26. The method of claim 25, further comprising:
2 decoding the received frame in accordance with a plurality of rate
hypotheses to generate a plurality of decoded frames.

27. The method of claim 26, wherein the frame rate of the received frame
2 is detected based on results of a CRC check on the plurality of decoded frames.

28. The method of claim 27, wherein the frame rate of the received frame
2 is further detected based on symbol error rates for the plurality of decoded
frames.

29. The method of claim 25, wherein the received frame is associated
2 with one of a plurality of possible frame rates, and wherein the detecting is
performed in accordance with a rate detection algorithm (RDA).

30. The method of claim 29, wherein the plurality of possible frame rates
2 include four frame rates used for speech information, one frame rate used for a
silence descriptor (SID), and one frame rate used for a blank frame.

31. In a wireless communication systems, a transmitting entity operative
2 to transmit data bits associated with an adaptive multi-rate (AMR) speech
coder, comprising:
4 a frame quality generator configured to process a plurality of data bits
associated with the AMR speech coder to generate a plurality of frame quality
6 indicator bits;
a frame formatter coupled to the frame quality generator and configured
8 to form a formatted frame having included therein the plurality of data bits and
the plurality of frame quality indicator bits and conforming to a particular
10 frame format defined by the communication system; and
a transmitter unit configured to transmit a representation of the
12 formatted frame.

32. The transmitting entity of claim 31, further comprising:
2 a convolutional encoder coupled to the frame formatter and configured
to encode the formatted frame to generate an encoded frame.

33. In a wireless communication systems, a receiving entity operative to
2 receive data bits associated with an adaptive multi-rate (AMR) speech coder,
comprising:
4 a decoder configured to receive a frame having included therein a
plurality of data bits associated with the AMR speech coder, decode the
6 received frame in accordance with a plurality of rate hypotheses, and provide a
plurality of decoded frames for the plurality of rate hypotheses, wherein each
8 rate hypothesis correspond to one of a plurality of possible frame rates for the
received frame; and
10 a rate detector coupled to the decoder and configured to receive at least
one set of quality indicator values, determine a particular frame rate for the
12 received frame based on the at least one set of quality indicator values, and
extract the plurality of data bits from the received frame based at least in part
14 on the determined frame rate.

34. The receiving entity of claim 33, wherein the rate detector includes

- 2 a CRC checker configured to check the plurality of decoded frames
based on a set of CRC bits included each decoded frame, and to provide a
4 plurality of check bits indicative of results of the CRC check for the plurality of
decoded frames.

35. The receiving entity of claim 33, wherein the rate detector includes
2 a symbol error rate (SER) detector configured to provide a plurality of
SER values for the plurality of decoded frames.

36. The receiving entity of claim 33, wherein the rate detector includes
2 a Yamamoto detector configured to provide a plurality of Yamamoto
values for the plurality of decoded frames.

37. The receiving entity of claim 33, wherein the frame rate of the
2 received frame is determined based on results of CRC check, symbol error
rates, Yamamoto values, or a combination thereof, obtained for the plurality of
4 decoded frames.

38. A method for sending adaptive multi-rate (AMR) speech coder
2 information in a cdma2000 system, comprising:
encoding bits of the AMR speech coder information using a cyclic
4 redundancy check (CRC);
inserting the AMR speech coder information into a cdma2000 frame
6 having a frame rate selected from a particular number of possible frame rates;
and
8 transmitting a representation of the cdma2000 frame.

39. A method of receiving adaptive multi-rate (AMR) speech coder
2 information in a cdma2000 system, comprising:
performing rate detection on a received cdma2000 frame to determine a
4 frame rate of the received frame; and
extracting a plurality of AMR information bits from the received frame
6 based at least in part on the determined frame rate of the received frame.

40. The method of claim 2, wherein the particular encoder is a
2 convolutional encoder.

41. The method of claim 2, wherein the formatted frame includes a
2 plurality of tail bits used to set the convolutional encoder to a known state at
the start of each frame.

42. The method of claim 9, further comprising:
2 omitting, from the formatted frame, format bits indicative of a particular
data rate of the speech information included in the formatted frame.

43. The method of claim 1, further comprising:
2 omitting from the formatted frame signaling information associated with
AMR data.

44. The method of claim 38, further comprising:
2 encoding the AMR speech coder information according to a tailed-off
convolutional code.

45. The method of claim 38, wherein the bits of the AMR speech coder
2 information fall into a particular number of priority classes corresponding to
different levels of importance.

46. The method of claim 45, wherein the particular number of priority
2 classes is three.

47. The method of claim 38, wherein the particular number of possible
2 frame rates is six.

48. The method of claim 47, wherein the six possible frame rates
2 includes four frame rates used to carry primary service option data, one frame
rate used to carry silence descriptor (SID) data, and one frame rate used to
4 carry no data.

49. The method of claim 48, further comprising:
2 inserting one or more format bits in each frame carrying SID data to
form a frame having a particular number of total bits.

50. The method of claim 49, wherein a frame carrying SID data includes
2 43 total bits.

51. The method of claim 38, further comprising:
2 sending signaling information on a cdma2000 dedicated control channel
(DCCH) channel.

52. The method of claim 38, further comprising:
2 sending signaling information using blank-and-burst frames on a
cdma2000 fundamental channel.

53. The method of claim 39, further comprising:
2 selecting a frame rate for the received frame from among a particular
number of possible frame rates based on a blind rate determination algorithm.

54. The method of claim 53, wherein the particular number of possible
2 frame rates is six.

55. The method of claim 54, wherein the six possible frame rates
2 includes four frame rates used to carry primary service option data, one frame
rate used to carry silence descriptor (SID) data, and one frame rate used to
4 carry no data.

56. The method of claim 39, further comprising:
2 receiving on a cdma2000 dedicated control channel (DCCH) channel
signaling information associated with a traffic channel carrying the AMR
4 speech coder information.

57. The method of claim 39, further comprising:
2 receiving signaling information associated with a fundamental channel
carrying the AMR speech coder information within blank-and-burst frames
4 received in the fundamental channel.

INTERNATIONAL SEARCH REPORT

International Application No.

PCT/US 01/00706

A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 H04L1/20 H04L1/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 H04L

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, WPI Data, PAJ, INSPEC

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	WO 99 60742 A (CONEXANT SYSTEMS INC) 25 November 1999 (1999-11-25) abstract claims 1,2,23-28; figure 2	1-4,6,8, 9,11, 25-28
Y	WO 99 48237 A (NOKIA TELECOMMUNICATIONS OY ;MIKKOLA HANNU (FI); VAINIO JANNE (FI)) 23 September 1999 (1999-09-23) abstract page 6, line 32 -page 7, line 24 claims 1-12; figures 3,5	1-4,6,8, 9,11, 25-28

☐ Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents:

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

G document member of the same patent family

Date of the actual completion of the international search

22 May 2001

Date of mailing of the international search report

01/06/2001

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2
